Introduction and Scope

This Annex presents a series of figures showing global and regional patterns of climate change computed from global climate model output gathered as part of the Coupled Model Intercomparison Project Phase 5 (CMIP5; Taylor et al., 2012). Maps of surface air temperature change and relative precipitation change (i.e., change expressed as a percentage of mean precipitation) in different seasons are presented for the globe and for a number of different sub-continental-scale regions. Twenty-year average changes for the near term (2016–2035), for the mid term (2046–2065) and for the long term (2081–2100) are given, relative to a reference period of 1986–2005. Time series for temperature and relative precipitation changes are shown for global land and sea averages, the 26 sub-continental SREX (IPCC Special Report on Managing the Risks of Extreme Events and Disasters to Advance Climate Change Adaptation) regions (IPCC, 2012) augmented with polar regions and the Caribbean, two Indian Ocean and three Pacific Ocean regions. In total this Annex gives projections for 35 regions, 2 variables and up to 4 seasons, along with the annual mean. The projections are made under the Representative Concentration Pathway (RCP) scenarios, which are introduced in Chapter 1, with more technical detail given in Section 12.3 (also note the discussion of near-term biases in Sections 11.3.5.1 and 11.3.6.1). Maps are shown only for the RCP4.5 scenario; however, the time series presented show how the global-average change varies among the RCP2.6, RCP4.5, RCP6.0 and RCP8.5 scenarios. Spatial maps for the other RCP scenarios are presented in the corresponding Supplementary Material. Figures AI.SM4.5.1 and AI.SM4.5.2 give a graphical explanation of aspects of both the time series plots and the spatial maps. While some of the background to the information presented is given here, discussion of the maps and time series, as well as important additional background, is provided in Chapters 9, 11, 12 and 14. Figure captions on each page of the Atlas reference the specific sub-sections in the report relevant to the regions considered on that page.

The projection of future climate change involves the careful evaluation of models, taking into account uncertainties in observations and consideration of the physical basis of the findings, in order to characterize the credibility of the projections and assess their sensitivity to uncertainties. As discussed in Chapter 9, different climate models have varying degrees of success in simulating past climate variability and mean state when compared to observations. Verification of regional trends is discussed in Box 11.2 and provides further information on the credibility of model projections. The information presented in this Annex is based entirely on all available CMIP5 model output, with equal weight given to each model or version with different parameterizations.

Complementary methods for making quantitative projections, in which model output is combined with information about model performance using statistical techniques, exist and should be considered in impacts studies (see Sections 9.8.3, 11.3.1 and 12.2.2 to 12.2.3). Although results from the application of such methods can be assessed alongside the projections from CMIP5 presented here, it is beyond the scope of this Annex. Nor do the simple maps provided represent a robust estimate of the uncertainty associated with the projections. Here the range of model spread is provided as a simple, albeit imperfect guide, to the range of possible futures (including the effect of natural variability).

Alternative approaches used to estimate projection uncertainty are discussed in Sections 11.3.1 and 12.2.2 to 12.2.3. The reliability of past trends is assessed in Box 11.2, which concludes that the time series and maps cannot be interpreted literally as probability density functions. They should not be interpreted as ‘forecasts’.

Projections of future climate change are conditional on assumptions of climate forcing, affected by shortcomings of climate models and inevitably also subject to internal variability when considering specific periods. Projected patterns of climate change may differ from one climate model generation to the next due to improvements in models. Some model inadequacies are common to all models, but so are many patterns of change across successive generations of models, which gives some confidence in projections. The information presented is intended to be only a starting point for anyone interested in more detailed information on projections of future climate change and complements the assessment in Chapters 11, 12 and 14.

Technical Notes

Data and Processing: The figures have been constructed using the CMIP5 model output available at the time of the AR5 cut-off for accepted papers (15 March 2013). This data set comprises 32/42/25/39 scenario experiments for RCP2.6/4.5/6.0/8.5 from 42 climate models (Table AI.SM4.5.1). Only concentration-driven experiments are used (i.e., those in which concentrations rather than emissions of greenhouse gases are prescribed) and only one ensemble member from each model is selected, even if multiple realizations exist with different initial conditions and different realizations of natural variability. Hence each model is given equal weight. Maps from only one scenario (RCP4.5) are shown in this Annex I Supplementary Material file.

Reference Period: Projections are expressed as anomalies with respect to the reference period of 1986–2005 for both time series and spatial maps (i.e., differences between the future period and the reference period). Thus the changes are relative to the climate change that has already occurred since the pre-industrial period and which is discussed in Chapters 2 and 10. For quantities where the trend is larger than the natural variability such as large-area temperature changes, a more recent reference period would give better estimates (see Section 11.3.6.1); for quantities where the natural variability is much larger than the trend a longer reference period would be preferable.

Equal Model Weighting: Model evaluation uses a multitude of techniques (see Chapter 9) and there is no consensus in the community about how to use this information to assign likelihood to different model projections. Consequently, the different CMIP5 models used for the projections in the Atlas are all considered to give equally likely projections in the sense of ‘one model, one vote’. Models with variations in physical parameterization schemes are treated as distinct models.

Variables: Two variables have been plotted: surface air temperature change and relative precipitation change. The relative precipitation change is defined as the percentage change from the 1986–2005 reference period in each ensemble member. For the time series, the variables are first averaged over the domain and then the changes from the
reference period are computed. This implies that in regions with large
climatological precipitation gradients, the change is generally domi-
nated by the areas with the most precipitation.

**Seasons:** For temperature, the standard meteorological seasons June
to August and December to February are shown, as these often corre-
spond roughly with the warmest and coldest seasons. The annual mean
and remaining seasons, March to May and September to October, are
also included in this Supplementary Material. For precipitation, the
half-years April to September and October to March are shown, so that
in most monsoon areas the local rain seasons are entirely contained
within the seasonal range plotted. Because the seasonal average is
computed first, followed by the percentile change, these numbers are
dominated by the rainy months within the half-year. The annual means
are also included in this Supplementary Material.

**Regions:** In addition to the global maps, the areas defined in the SREX
(IPCC, 2012) are plotted with the addition of six regions containing the
Caribbean, Indian Ocean and Pacific Island States and land and sea
areas of the two polar regions. For regions containing large land areas,
averages are computed only over land grid points only. For ocean
regions, averages are computed over both land and ocean grid points
(see figure captions). A grid box is considered land if the land fraction
is larger than 50% and sea if it is smaller than this. SREX regions with
long coastlines (west coast of South America, North Europe, Southeast
Asia) therefore include some influence of the ocean. Note that temper-
ature and precipitation over islands may be very different from those
over the surrounding sea.

**Time Series:** For each of the resulting areas the areal mean is comput-
ed on the original model grid using land, sea or all points, depending on
the definition of the region (see above). As an indication of the model
uncertainty and natural variability, the time series of each model and
scenario over the common period 1900–2100 are shown on the top of
the page as anomalies relative to 1986–2005 (the seasons December
to February and October to March are counted towards the second
year in the interval). The multi-model ensemble means are also shown.
Finally, for the period 2081–2100, the 20-year means are computed
and the box-and-whisker plots show the 5th, 25th, 50th (median),
75th and 95th percentiles sampled over the distribution of the 20-year
means of the model time series indicated in Table AI.SM4.5.1, includ-
ing both natural variability and model spread. In the 20-year means
the natural variability is suppressed relative to the annual values in
the time series whereas the model uncertainty is the same. Note that
owing to a smaller number of models, the box-and-whisker plots for the
RCP2.6 scenario and especially the RCP6.0 scenario are less certain
than those for RCP4.5 and RCP8.5.

**Spatial Maps:** The maps in the Atlas show, for an area encompassing
two or three regions, the difference between the periods 2016–2035,
As local projections of climate change are uncertain, a measure of
the range of model projections is shown in addition to the median
response of the model ensemble interpolated to a common 2.5° grid
(the interpolation was done bilinearly for surface air temperature and
first order conservatively for precipitation). It should again be empha-
sized (see above) that this range does not represent the full uncertainty
in the projection. On the left, the 25th percentile of the distribution
of ensemble members is shown; on the right, the 75th percentile.
The median is shown in the middle (different from similar plots in Chapters
11 and 12 and the time series which show the multi-model mean).
The distribution combines the effects of natural variability and model
spread. The colour scale is kept constant over all maps.

**Hatching:** Hatching indicates regions where the magnitude of the change
of the 20-year mean is less than 1 standard deviation of model-
estimated present-day natural variability of 20-year mean differences.
The natural variability is estimated using all pre-industrial control runs
which are at least 500 years long. The first 100 years of the pre-indus-
trial are ignored. The natural variability is then calculated for every grid
point as the standard deviation of non-overlapping 20-year means
after a quadratic fit is subtracted at every grid point to eliminate model
drift. This is multiplied by the square root of 2, a factor that arises as
the comparison is between two distributions of numbers. The median
across all models of that quantity is used. This characterizes the typical
difference between two 20-year averages that would be expected due
to unforced internal variability. The hatching is applied to all maps so,
for example, if the 25th percentile of the distribution of model pro-
jections is less than 1 standard deviation of natural variability, it is
hatched.

The hatching can be interpreted as some indication of the strength
of the future anomalies from present-day climate, when compared to
the strength of present-day internal 20-year variability. It either means
that the change is relatively small or that there is little agreement
between models on the sign of the change. It is presented only as a
guide to assessing the strength of change as the difference between
two 20-year intervals. Using other measures of natural variability
would give smaller or larger hatched areas, but the colours underneath
the hatching would not be very different. Other methods of hatching
and stippling are possible (see Box 12.1) and, in cases where such
information is critical, it is recommended that thorough attention is
paid to assessing significance using a statistical test appropriate to the
problem being considered.

Table AI.SM4.5.1 | The CMIP5 models used in this Annex for each of the historical and RCP scenario experiments. A number in each column is the identifier of the single ensemble member from that model that is used. A blank indicates no run was used, usually because that scenario run was not available. For the pre-industrial control column (piControl), a ‘tas’ indicates that those control simulations are used in the estimate of internal variability of surface air temperature and a ‘pr’ indicates that those control simulations are used in the estimate of precipitation internal variability.

For each point, the 25th, 50th and 75th percentiles of the distribution of the CMIP5 ensemble are shown; this includes both natural variability and inter-model spread. Hatching denotes areas where the 20-year mean differences of the percentiles are less than the standard deviation of model-estimated present-day natural variability of 20-year mean differences.

Sections 9.4.1.1, 9.6.1.1, 10.3.1.1.4, 11.3.2.1.2, 11.3.3.1, Box 11.2, 12.4.3.1 and 12.4.7 contain relevant information regarding the evaluation of models in this region, the model spread in the context of other methods of projecting changes and the role of modes of variability and other climate phenomena.
Figure AI.SM4.7 | (Top left) Time series of temperature change relative to 1986–2005 averaged over land grid points over the globe in June to August. (Top right) Same for sea grid points. Thin lines denote one ensemble member per model, thick lines the CMIP5 multi-model mean. On the right-hand side the 5th, 25th, 50th (median), 75th and 95th percentiles of the distribution of 20-year mean changes are given for 2081–2100 in the four RCP scenarios.

(Below) Maps of temperature changes in 2016–2035, 2046–2065 and 2081–2100 with respect to 1986–2005 in the RCP4.5 scenario. For each point, the 25th, 50th and 75th percentiles of the distribution of the CMIP5 ensemble are shown; this includes both natural variability and inter-model spread. Hatching denotes areas where the 20-year mean differences of the percentiles are less than the standard deviation of model-estimated present-day natural variability of 20-year mean differences.

For each point, the 25th, 50th and 75th percentiles of the distribution of the CMIP5 ensemble are shown; this includes both natural variability and inter-model spread. Hatching denotes areas where the 20-year mean differences of the percentiles are less than the standard deviation of model-estimated present-day natural variability of 20-year mean differences.

Sections 9.4.1.1, 9.6.1.1, 10.3.2.2, 11.3.2.3.1, Box 11.2, 12.4.5.2, 14.8.2, 14.8.8 contain relevant information regarding the evaluation of models in this region, the model spread in the context of other methods of projecting changes and the role of modes of variability and other climate phenomena.
Figure AI.SM4.5.26 | (Top left) Time series of relative change relative to 1986–2005 in precipitation averaged over land grid points in Canada/Greenland/Iceland (50°N to 85°N, 105°W to 10°W) in October to March. (Top right) Same for land grid points in North Asia (50°N to 70°N, 40°E to 180°E). Thin lines denote one ensemble member per model, thick lines the CMIP5 multi-model mean. On the right-hand side the 5th, 25th, 50th (median), 75th and 95th percentiles of the distribution of 20-year mean changes are given for 2081–2100 in the four RCP scenarios.

(Below) Maps of precipitation changes in 2016–2035, 2046–2065 and 2081–2100 with respect to 1986–2005 in the RCP4.5 scenario. For each point, the 25th, 50th and 75th percentiles of the distribution of the CMIP5 ensemble are shown; this includes both natural variability and inter-model spread. Hatching denotes areas where the 20-year mean differences of the percentiles are less than the standard deviation of model-estimated present-day natural variability of 20-year mean differences.

Sections 9.4.1.1, 9.6.1.1, 11.3.2.1.2, Box 11.2, 14.2.3.2, 14.8.5 contain relevant information regarding the evaluation of models in this region, the model spread in the context of other methods of projecting changes and the role of modes of variability and other climate phenomena.
Figure AI.SM.4.60 | (Top left) Time series of annual temperature change relative to 1986–2005 averaged over land grid points in the west coast of South America (79.7°W, 1.2°S; 66.4°W, 20°S; 72.1°W, 50°S; 67.3°W, 56.7°S; 82.0°W, 56.7°S; 82.2°W, 0.5°N). (Top right) Same for land grid points in southeastern South America (39.4°W, 20°S; 39.4°W, 56.6°S; 67.3°W, 56.7°S; 72.1°W, 50°S; 66°W, 20°S). Thin lines denote one ensemble member per model, thick lines the CMIP5 multi-model mean. On the right-hand side the 5th, 25th, 50th (median), 75th and 95th percentiles of the distribution of 20-year mean changes are given for 2081–2100 in the four RCP scenarios.

(Below) Maps of temperature changes in 2016–2035, 2046–2065 and 2081–2100 with respect to 1986–2005 in the RCP4.5 scenario. For each point, the 25th, 50th and 75th percentiles of the distribution of the CMIP5 ensemble are shown; this includes both natural variability and inter-model spread. Hatching denotes areas where the 20-year mean differences of the percentiles are less than the standard deviation of model-estimated present-day natural variability of 20-year mean differences.

Sections 9.4.1.1, 9.6.1.1, 10.3.1.1.4, Box 11.2, 14.8.5 contain relevant information regarding the evaluation of models in this region, the model spread in the context of other methods of projecting changes and the role of modes of variability and other climate phenomena.
Figure AI.SM4.5.61 | (Top left) Time series of temperature change relative to 1986–2005 averaged over land grid points in the west coast of South America (72.1°W, 50°S; 67.3°W, 56.7°S; 82.0°W, 56.7°S; 82.2°W, 0.5°N) in December to February. For each point, the 25th, 50th and 75th percentiles of the distribution of the CMIP5 ensemble are shown; this includes both natural variability and inter-model spread. Hatching denotes areas where the 20-year mean differences of the percentiles are less than the standard deviation of model-estimated present-day natural variability of 20-year mean differences.

Sections 9.4.1.1, 9.6.1.1, Box 11.2, 12.4.5.2, 14.8.6 contain relevant information regarding the evaluation of models in this region, the model spread in the context of other methods of projecting changes and the role of modes of variability and other climate phenomena.
Figure AI.SM4.5.76 | (Top left) Time series of annual temperature change relative to 1986–2005 averaged over land grid points in the region South Europe/Mediterranean (30°N to 45°N, 10°W to 40°E). (Top right) Same for land grid points in the Sahara (15°N to 30°N, 20°W to 40°E). Thin lines denote one ensemble member per model; thick lines the CMIP5 multi-model mean. On the right-hand side the 5th, 25th, 50th (median), 75th and 95th percentiles of the distribution of 20-year mean changes are given for 2081–2100 in the four RCP scenarios.

(Below) Maps of temperature changes in 2016–2035, 2046–2065 and 2081–2100 with respect to 1986–2005 in the RCP4.5 scenario. For each point, the 25th, 50th and 75th percentiles of the distribution of the CMIP5 ensemble are shown; this includes both natural variability and inter-model spread. Hatching denotes areas where the 20-year mean differences of the percentiles are less than the standard deviation of model-estimated present-day natural variability of 20-year mean differences.

Figure AI.SM4.5.112 | (Top left) Time series of temperature change relative to 1986–2005 averaged over land grid points in Eastern Asia (20°N to 50°N, 100°E to 145°E) in September to November. (Top right) Same for land grid points on the Tibetan Plateau (30°N to 50°N, 75°E to 100°E). Thin lines denote one ensemble member per model, thick lines the CMIP5 multi-model mean. On the right-hand side the 5th, 25th, 50th (median), 75th and 95th percentiles of the distribution of 20-year mean changes are given for 2081–2100 in the four RCP scenarios.

(Below) Maps of temperature changes in 2016–2035, 2046–2065 and 2081–2100 with respect to 1986–2005 in the RCP4.5 scenario. For each point, the 25th, 50th and 75th percentiles of the distribution of the CMIP5 ensemble are shown; this includes both natural variability and inter-model spread. Hatching denotes areas where the 20-year mean differences of the percentiles are less than the standard deviation of model-estimated present-day natural variability of 20-year mean differences.

Sections 9.4.1.1, 9.6.1.1, 10.3.1.1.4, Box 11.2, 14.8.8, 14.8.9 contain relevant information regarding the evaluation of models in this region, the model spread in the context of other methods of projecting changes and the role of modes of variability and other climate phenomena.
Figure AI.SM4.113 | (Top left) Time series of relative change relative to 1986–2005 in annual precipitation averaged over land grid points in Eastern Asia (20°N to 50°N, 100°E to 145°E). (Top right) Same for land grid points on the Tibetan Plateau (30°N to 50°N, 75°E to 100°E). Thin lines denote one ensemble member per model, thick lines the CMIP5 multi-model mean. Figure AI.SM4.5.130 | (Top left) Time series of relative change relative to 1986–2005 in precipitation averaged over land grid points in Southeast Asia (10°S to 20°N, 95°E to 155°E) in October to March. (Top right) Same for sea grid points. Thin lines denote one ensemble member per model, thick lines the CMIP5 multi-model mean. On the right-hand side the 5th, 25th, 50th (median), 75th and 95th percentiles of the distribution of 20-year mean changes are given for 2081–2100 in the four RCP scenarios.

(Below) Maps of precipitation changes in 2016–2035, 2046–2065 and 2081–2100 with respect to 1986–2005 in the RCP4.5 scenario. For each point, the 25th, 50th and 75th percentiles of the distribution of the CMIP5 ensemble are shown; this includes both natural variability and inter-model spread. Hatching denotes areas where the 20-year mean differences of the percentiles are less than the standard deviation of model-estimated present-day natural variability of 20-year mean differences.

Sections 9.4.1.1, 9.6.1.1, Box 11.2, 14.2.2.3, 14.2.2.5, 14.8.12 contain relevant information regarding the evaluation of models in this region, the model spread in the context of other methods of projecting changes and the role of modes of variability and other climate phenomena.
Figure AI.SM4.131 | (Top left) Time series of relative change relative to 1986–2005 in precipitation averaged over land grid points in Southeast Asia (10°S to 20°N, 95°E to 155°E) in April to September. (Top right) Same for sea grid points. Thin lines denote one ensemble member per model, thick lines the CMIP5 multi-model mean. On the right-hand side the 5th, 25th, 50th (median), 75th and 95th percentiles of the distribution of 20-year mean changes are given for 2081–2100 in the four RCP scenarios.

(Below) Maps of precipitation changes in 2016–2035, 2046–2065 and 2081–2100 with respect to 1986–2005 in the RCP4.5 scenario. For each point, the 25th, 50th and 75th percentiles of the distribution of the CMIP5 ensemble are shown; this includes both natural variability and inter-model spread. Hatching denotes areas where the 20-year mean differences of the percentiles are less than the standard deviation of model-estimated present-day natural variability of 20-year mean differences.

Sections 9.4.1.1, 9.6.1.1, 11.3.2.1.2, Box 11.2, 12.4.5.2, 14.8.14 contain relevant information regarding the evaluation of models in this region, the model spread in the context of other methods of projecting changes and the role of modes of variability and other climate phenomena.
Figure AISM4.5.148  |  (Top left) Time series of annual temperature change relative to 1986–2005 averaged over land grid points in Antarctica (90°S to 50°S). (Top right) Same for sea grid points. Thin lines denote one ensemble member per model, thick lines the CMIP5 multi-model mean. On the right-hand side the 5th, 25th, 50th (median), 75th and 95th percentiles of the distribution of 20-year mean changes are given for 2081–2100 in the four RCP scenarios.
